

The Flu Can Be Devastating For Adults 65+

According to the Public Health Agency of Canada, adults aged 65 and older are at high risk of complications from influenza infection – also called ‘the flu’.

What should you know?

While adults age 65+ represent approximately 15–17% of the Canadian population, they have accounted for up to:

70% of flu-related hospitalizations
91% of flu-related deaths

Vaccination is the most effective way to prevent infection from the influenza virus. However, not all influenza vaccines are equally effective in adults aged 65 and older.

Why is this important?

Adults age 65 and older are more severely affected by flu because:

- the immune system becomes weaker with age and, as such, does not respond as well to standard flu vaccination,
- they have less ability to fight the infection,
- the flu can worsen pre-existing chronic conditions such as diabetes, heart disease or renal disease.

How can getting the flu be dangerous for older adults?

The flu is different from a cold. The symptoms of flu infection—like body aches, fever, cough, headache, loss of appetite, chills, sore throat and fatigue—can be more severe and may require people to stay in bed for several days.

Although the flu is difficult for everyone, it can have serious consequences for people aged 65 and older because, with age, the immune system becomes weaker and less able to fight infection.

People aged 65 and older are at a much higher risk of flu infection and its consequences than younger adults.

Also, those over 65 are at a high risk of flu-related complications or hospitalization should they have chronic health conditions such as:

Lung disease	Cardiac (heart or blood vessel) disease
Diabetes	Renal (kidney) disease
Anemia	Neurologic conditions (e.g., seizures)

The flu is also known to worsen pre-existing medical conditions such as heart disease. Research has shown that flu can trigger heart attacks and strokes in individuals who have heart disease.

What you can do.

Ask your doctor about the different flu vaccines that are available, and which ones may be best suited for you.

Vaccination is the most effective way to prevent flu.

Flu vaccines help your body build its own defences so it can do a better job of preventing or fighting infection caused by influenza virus.

Flu vaccines are prepared specifically for each season.

Vaccination before the beginning of the flu season is recommended.
